Background & Objective: It is not clear whether activated lymphocytes of patients with systemic lupus erythematosus (SLE) are more proliferative or less apoptotic. We aimed to delineate potential differences between B and T cells of SLE patients compared to healthy controls regarding the telomerase activity and apoptosis status.

Methods: In this cross-sectional case control study, Blood samples were taken from 10 SLE patients and 10 healthy controls. B and T cells were separated using magnetic cell sorting system. Telomeric repeat amplification protocol (TRAP) assay and real-time PCR were used to determine the telomerase activity and the expression of alternatively spliced variants.

Results: Four patients under treatment showed significant telomerase activity in their T cells. Four of the newly diagnosed patients showed telomerase activity in their B cells (20% of all patients and 40% of new onset patients). There was no specific pattern of human telomerase reverse transcriptase variant expression within the patients' lymphocytes. A significantly reduced expression of Bcl-2 was detected in B cells (P=0.018) and a trend toward lower Bcl-2 expression in T cells was seen in SLE patients compared to healthy controls.

Conclusion: Although not definitive, our results may suggest that B cells may have more active roles during the earlier phases of the disease attack, while T cells take over when the disease reaches its chronic stages.

Introduction

Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that can cause dysfunction of multiple body organs such as the skin, joints, nervous system, kidneys, heart and hematopoietic system. Much evidence shows contribution of both adaptive and innate immunity in the pathogenesis of the disease, while T cell dependent B cell activation has a central role in this scenario (1,2).

Like other cells, proliferation and expansion of the lymphocytes is dependent on the activation of the cell cycle, for which stability of chromosomal telomere is critical. Maintenance of telomere by itself relies on the function of telomerase enzyme complex which is composed of an RNA subunit, human telomerase RNA (hTR), and a protein component, human telomerase reverse transcriptase (hTERT) (3). Literature shows the existence of multiple alternative splicing variants for hTERT, which take part in regulation of telomerase activity (4,5). Studies on different cell types have shown that spliced variants α deletion and β deletion are the most abundant variants of hTERT (6).

Subsequent to lymphocyte activation and proliferation, different mechanisms may act to subside the activation status of these cells and keep homeostasis. Apoptosis is one of the mechanisms which can be triggered by different pathways (7). External pathway initiates by interaction of the ligands

Introduction

Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that can cause dysfunction of multiple body organs such as the skin, joints, nervous system, kidneys, heart and hematopoietic system. Much evidence shows contribution of both adaptive and innate immunity in the pathogenesis of the disease, while T cell dependent B cell activation has a central role in this scenario (1,2).

Like other cells, proliferation and expansion of the lymphocytes is dependent on the activation of the cell cycle, for which stability of chromosomal telomere is critical. Maintenance of telomere by itself relies on the function of telomerase enzyme complex which is composed of an RNA subunit, human telomerase RNA (hTR), and a protein component, human telomerase reverse transcriptase (hTERT) (3). Literature shows the existence of multiple alternative splicing variants for hTERT, which take part in regulation of telomerase activity (4,5). Studies on different cell types have shown that spliced variants α deletion and β deletion are the most abundant variants of hTERT (6).

Subsequent to lymphocyte activation and proliferation, different mechanisms may act to subside the activation status of these cells and keep homeostasis. Apoptosis is one of the mechanisms which can be triggered by different pathways (7). External pathway initiates by interaction of the ligands
to death receptors of the cells, while the internal pathway originates from the mitochondria. Several factors contribute to the apoptosis process and control of the pathways. Within the intrinsic pathway, some members of Bcl-2 family act as pro-apoptotic factors, while others work to halt the pathway (8).

We hypothesized that in SLE patients, the variation in factors controlling proliferation and survival of lymphocytes may contribute to improper activation of the lymphocytes and hence autoimmunity. Therefore, in this study we investigated the possible variation in the expression of the alternative splicing forms of hTERT and correlated them with the findings related to the expression of bcl2, anti-apoptotic factor in the same patients and compared them with the results obtained from healthy individuals.

Materials and Methods

Patients and Controls

Ten female patients who were admitted in Hafez hospital, Shiraz, Iran, from January to May 2015 with definite diagnosis of SLE and ten healthy volunteers were recruited in this study. Co-existence of malignancy was considered as the exclusion criteria. Of them, five patients were newly diagnosed SLE patients who had not received immunomodulatory medications. The other five patients were under treatment with medications. Healthy controls were women in the same range of age as the patients and had not received immunosuppressive medications during or before the study, or had any chronic inflammatory conditions such as atherosclerotic cardiovascular disease, Diabetes mellitus, and degenerative joint disorders. The study was approved for them and a written consent was taken from all the participants. The study was approved by the ethics committee of Shiraz University of Medical Sciences. Peripheral blood samples of 20 mL were taken by venipuncture with EDTA solution (10 μL of 0.5 M stock) as anticoagulant.

Isolation of B and T cells

Peripheral blood mononuclear cells (PBMC) were isolated using gradient density centrifugation on ficoll-Hypaque (Lymphodex, Inno-Train). The layer of mononuclear cells was isolated, and the number of isolated cells was determined using a hemocytometer.

CD3+ and CD19+ cells were purified from the PBMCs using magnetic micro-beads coated with anti-CD3 or CD19 antibodies, respectively, according to the manufacturer’s instruction (Miltenyibiotec, Germany).

Flow Cytometry

Flow cytometry analysis was used for further characterization of the purified cells using Fluorescein isothiocyanate (FITC) conjugated mouse anti-human monoclonal antibodies against CD3, CD4, CD45 and Phycocerythrin (PE) conjugated antibodies against CD8, CD14, CD16, CD19 and CD56, in different combinations. All antibodies were purchased from Abcam, UK. The cells were suspended in FACS buffer containing 2% fetal bovine serum and stained with appropriate amounts of antibodies at 4°C in dark. Mouse IgG1 and IgG2 isotypes antibody controls were used as negative control to determine the possible non-specific staining. A four color FACS Caliber instrument with Cell Quest Pro acquisition software (BD, US) was used to test the cells. Flow data were analyzed and graphically presented with Win MDI software.

Quantitative RT-PCR

The total RNA of the purified cells was extracted by Trizol reagent (Invitrogen, USA) in accordance with the manufacturer’s instructions. RNA samples were treated with DNase I (Fermentas, Vilnius, Lithuania) to remove the genomic DNA contamination. cDNA was synthesized from 5μg of the total RNA with the Revert Aid H minus First Strand cDNA Synthesis Kit (Fermentas, Lithuania).

The hTERT variant transcripts were measured by real time PCR, using specific primer sets for each variant (α-deletion, β-deletion, αβ-deletion and Full length) (Table 1) and sybr green 1 (Applied Biosystems, USA) as reporter dye on Chromo4 Detector thermal cycler (Bio-Rad, USA). Primer-Blast online freeware (http://www.ncbi.nlm.nih.gov/tools/primer-blast/) was used to design specific primers. Expression of β-actin was used as a housekeeping gene in analysis.

Figure 1 shows the location of deletions and the binding sites of the designed primers on hTERT mRNA.

PCR reactions were set up in a final volume of 20 μL reaction. The mixture contained master mix, 0.5 μg of cDNA and 100nM of each primer. The cycling program comprised of an initial denaturation at 95°C for 10 min and 45 cycles of denaturation at 95°C for 15s, annealing at 60°C for 50s, extension at 78°C for 34s. Fluorescence emission was collected at the end of the extension time. The specificity of amplifications was confirmed by melting curve analysis. Relative expression of hTERT variants was calculated by 2-ΔΔCt formula. Relative expression of Bcl-2 was relatively quantified against 18sRNA housekeeping gene in the purified B cells and T cells of patients and healthy controls by real time PCR. Table 1 displays the sequence of forward and reverse primers used for analysis of expression pattern of the mentioned genes.

Quantitative Determination of Telomerase Activity

To quantify telomerase activity in B and T cells, the telomeric repeat amplification protocol (TRAP) assay was performed using the TeloTAGGG Telomerase PCR ELISA kit (Roche, Germany), according to the manufacturers’ instructions.

Statistical Analysis

The “one sample Kolmogorov-Smirnov” test was used to determine the distribution of data. Student t-test or by Mann–Whitney post-test was used to analyze the differences between the results based on data distribution. P value <0.05 was considered as statistically significant.

Results

Patient Data

SLE diagnosis of the patients who participated in this study was confirmed by clinical and laboratory data. Table 2 contains the demographic data and laboratory test results of the patients.

Purity of the Magnetic Cell Separation of T and B Lymphocytes

Magnetic beads and column were used to purify B and T lymphocytes from fresh blood samples. Flow cytometry analysis was used to assess the purity of the separated cells. Results showed that the mean purity of the isolated T cells was 98.4±0.8%, while 72.6±0.6% of them were CD4+ cells and 20.6±0.5% were CD8+ cells. CD19, CD16 and CD14 positive cells were all less than 0.5%. B-cell isolation also reached a similar purity and 87.4±0.9% of the purified cells were found CD19+. There were less than 0.5% of CD16 and CD14 positive cells in those preparations. However, a small fraction of CD3+ cells (8.4%±0.4%) could be detected in some preparations (Figure 2).

**Fig. 2.** FACS assessment of purity of B cells and T cells isolated with MACS. Mean purity of the isolated T cells is 98.4±0.8%, while 72.6±0.6% of them are CD4+ cells and 20.6±0.5% are CD8+ cells. CD19, CD16 and CD14 positive cells are all less than 0.5%. CD19+ cells constituted 87.4±0.9% of the purified B cells. There were less than 0.5% of CD16 and CD14 positive cells in B cell sample. A small fraction of CD3+ cells (8.4±0.4%) could be detected in B cell sample.
Different Patterns of Telomerase Activity in SLE Patients

Telomerase activity in the purified B and T lymphocytes was studied by TRAP assay. Based on that, there was no considerable telomerase activity in the B and T lymphocytes purified from healthy controls. However, among the patients, four patients who were receiving therapy had telomerase activity in their T cells (equivalent to 20% of all patients or 40% of patients under treatment), while no detectable activity was found in their B cells. On the other hand, telomerase activity was seen only in B cells, but not T cells, newly diagnosed SLE (2 patients; equivalent to 20% of all patients or 40% of newly diagnosed patients).

Expression of hTERT Variants by Purified Lymphocytes

Real time PCR was used to analyze the hTERT variants’ expression in the separated cells. Expression of hTERT was only observed in the samples that showed telomerase activity, i.e. B cell samples from two recently diagnosed patients and T cells from two other patients who were receiving immunosuppressant medication for a while. Although a variable expression pattern of four variants of hTERT was demonstrated by telomerase positive samples, dominant variants could be distinguished in each cell type on the basis of lower Ct values. The dominant variants in B cells with positive telomerase activity were β-variant and α/β-variant, while in two T cell samples with evident telomerase activity, the variant of no deletion and β-variant were dominant forms.

Expression of Bcl-2 as Anti-apoptosis Factor

Comparison of Bcl-2 expression showed significantly reduced expression of Bcl-2 in the B cells purified from SLE patients (P=0.018). Although T cells also showed decreased expression of Bcl-2, the difference was not statistically significant compared to healthy individuals (P=0.55) (Figure 3).

Discussion

Our results indicated the existence of potential differences between SLE patients (at different disease stages) and healthy individuals regarding telomerase activity and Bcl-2 expression in the T-B lymphocytes, in the absence of obvious correlations with specific hTERT splice variants. Although not definitive, our results may suggest that in SLE patients, B cells may have more active roles during the earlier phases of the disease attack, while T cells take over when the disease reaches its chronic stages. Higher apoptosis rate of the lymphocytes may be responsible for prolonged exposure of auto-antigens and participate in induction of autoimmunity. These suggestions need further evaluation.

Inappropriate activation and consequently survival of different subsets of the lymphocytes can result from turbulence in the homeostasis status of the immune system which causes autoimmunity. In general, resting peripheral blood lymphocytes like other somatic cells have very low to undetectable telomerase activity (9,10). However, upon activation, the lymphocytes up-regulate the telomerase activity (9,11). In this regard, several lines of evidence showed elevated telomerase activity in the peripheral blood lymphocytes of SLE patients (12-14). Similarly, in this study, we were able to show higher telomerase activity and more mRNA expression of hTERT in B cells from patients with new onset of SLE. In the same way, T cells from the patients under treatment for SLE had apparently higher telomerase activity.

When we studied the variants of hTERT in telomerase positive cells, we could not show the correlation between the telomerase activity and the expression of the alternative variants of hTERT in the B cells and T cells purified from SLE patients. This contrasts with what Jalink et al. showed where higher telomerase activity in activated normal T cells was in association with expression of full-length hTERT variant (15).
Having telomerase activity in the B cells, but not T lymphocytes, from newly diagnosed patients and more telomerase activity in only T cells from patients with chronic disease may raise suggestions about the discrimination of these two phases of the disease. Probably, B cells may have more active roles during the earlier phases of the disease attack, while T cells take over when the disease reaches its chronic stages or after therapy, despite the undeniable role of T cells in activation of B cells in early stages of SLE. Continuous activation of T cells and multiple rounds of cell division during the course of the disease cause shortening of the telomere in spite of the telomerase activity (16). Shorter telomere length in T cells, and not B cells, from SLE patients compared to healthy individuals supports such speculation (17,18).

The inability of the immune system to eliminate the auto-reactive lymphocytes through apoptosis has been considered as one possible mechanism of induction of autoimmunity (19). In this regard, some studies correlated the prolonged T cell life span of SLE patients to increased bcl-2 expression, as one of the main hallmarks of anti-apoptosis pathways (20,21). However, some studies showed increased apoptosis in the lymphocytes, particularly T cells from SLE patients (22-25), but with deficiency in the removal of the apoptotic debris (8,26,27). This can increase the chance of more exposure of the immune system to auto-antigens and induction of autoimmunity. We studied the expression of Bcl-2 in the purified B and T cells of SLE patients vs. healthy controls by real time PCR. Our results showed a substantial reduction in the expression of Bcl-2 gene in B cells and a non-significant reduction in T cells purified from SLE patients in comparison to healthy controls. These results are in line with the latter hypothesis of increased apoptosis of the lymphocytes in SLE patients. However, more detailed information is needed to reveal the malfunction of elements involved in this mechanism.

Our study had some limitation. The most important one is the small sample size. Results might be, however, useful as a platform for further evaluations in larger studies.

**Conclusion**

In conclusion, the altered pattern of telomerase activity in the B and T lymphocytes of SLE patients in addition to abnormal pattern of apoptosis or clearance of auto-antigens all together can make a platform of induction of auto-reactivity. Identification of defective elements in this pathway may provide potential therapeutic targets to restore the problem.
